Type Inference (I)

RESPONSE TO CRITICISMS OF TYPED LANGUAGES

- Types overly constrain functions & data
 - Polymorphism makes typed constructs useful in more contexts
 - universal polymorphism => code reuse

```
\circ \x.x : `a \rightarrow `a (* 'a is any type *)
```

- o reverse: 'a list → 'a list (* 'a is any type *)
- existential polymorphism => modules & abstract data types

```
 o T = ∃X {a:X; f:X → bool}
```

- \circ intT = {a: int; f: int \rightarrow bool}
- $obside boolT = {a: bool; f: bool → bool}$
- Types clutter programs and slow down programmer productivity
 - Type inference.
 - uninformative annotations may be omitted

Type Schemes

- A type scheme contains type variables that may be filled in during type inference
 - $s := 'a \mid int \mid bool \mid s1 \rightarrow s2$
 - 'a is a type variable (which stands for α)
- A term scheme is a term (a.k.a. expression) that contains type schemes rather than proper types
 - $e := ... \mid fun f (x:s1) : s2 = e$
 - Note the above *named function* notation

Untyped Language

EXAMPLE

```
fun map (f, l) =
  if null (l) then
    nil
  else
  cons (f (hd l), map (f, tl l)))
```

EXAMPLE library functions argument type is 'a list fun map (f, l) =if null (l) then nil else cons (f (hd l), map (f, tl l))) library function result type is 'a result type is 'a list argument type is ('a * 'a list)

result type is 'a list

STEP 1: ADD TYPE SCHEMES

```
fun map (f : a, l : b) : c =
   if null (l) then
      nil
   else
      cons (f (hd l), map (f, tl l)))
```

- walk over the program & keep track of the type equations t1 = t2 that must hold in order to type check the expressions according to the normal typing rules
- introduce new type variables for unknown types whenever necessary

```
fun map (f : a, l : b) : c =
   if null (l) then
        nil
   else
        cons (f (hd l), map (f, tl l)))
```

constraints b = b' list

```
fun map (f : a, l : b) : c =
   if null (l) then
        nil : d list
   else
        cons (f (hd l), map (f, tl l)))
```

constraints b = b' list

constraints b = b' list

constraints

b = b' list

b = b" list

b = b" list

```
fun map (f : a, l : b) : c =

if null (l) then

nil : d list

else

cons (f (hd l : b") : a', map (f, tl l) : c))
```

constraints

b = b' list b = b" list b = b"' list a = a b = b"' list

constraints

b = b' list b = b" list b = b"' list a = a b = b"' list a = b" -> a'

```
fun map (f : a, l : b) : c =
  if null (l) then
  nil : d list
  else
  cons (f (hd l), map (f, tl l))) : c' list
  d list = c' list
```

constraints b = b' list b = b" list b = b"' list a = a b = b"' list a = b" -> a'

c = c' list

a' = c'

```
fun map (f : a, l : b) : c =
  if null (l) then
      nil
   else
     cons (f (hd l), map (f, tl l)))
   : d list
        d list = c
```

constraints

b = b' list b = b" list b = b" list a = a b = b" list a = b" -> a' c = c' list a' = c' d list = c' list

```
fun map (f : a, l : b) : c =
   if null (l) then
      nil
   else
      cons (f (hd l), map (f, tl l)))
```

```
final
b = b' list
b = b" list
b = b" list
a = a
b = b" list
a = b" -> a'
c = c' list
a' = c'
d list = c' list
d list = c
```

STEP 3: SOLVE CONSTRAINTS

 Constraint solution provides all possible solutions to type scheme annotations on terms

```
final solution a = b' \rightarrow c' x : b' \text{ list} b = b' \text{ list} c = c' \text{ list} c = a
```

STEP 4: GENERATE TYPES

- Generate types from type schemes
 - Option 1: pick an instance of the most general type when we have completed type inference on the entire program
 - map : $((int \rightarrow int) * int list) \rightarrow int list$
 - Option 2: generate polymorphic types for program parts and continue (polymorphic) type inference
 - o map: \forall (a,b) ((a \rightarrow b) * a list) \rightarrow b list

QUIZ: GENERATING TYPES

Generate the polymorphic types for the following function:

```
fun fold (f, a, l) =
  case l of
    nil => a
    | h::t => fold (f, f (h, a), t)
```

Please show the intermedia steps and the equations that you are solving.

Type Inference Details

- Type constraints are sets of equations between type schemes
 - $q := \{s11 = s12, ..., sn1 = sn2\}$
 - eg: $\{b = b' \text{ list, } a = b \rightarrow c\}$

CONSTRAINT GENERATION

- Syntax-directed constraint generation
 - our algorithm crawls over abstract syntax of untyped expressions and generates
 - o a term scheme
 - o a set of constraints
- Algorithm defined as set of inference rules (as always).
- Judgement form:
 - G |-- u ==> e : t, q
 - u is untyped expression
 - e: t is a term scheme
 - q is a set of constraints

CONSTRAINT GENERATION

- Simple rules:
 - G $\mid --x ==> x : s, \{\}$ (if G(x) = s)
 - \circ If G(x) is not defined then x is free variable
 - G | -- 3 ==> 3 : int, {} (same for other ints)
 - G | -- true ==> true : bool, {}
 - G | -- false ==> false : bool, {}

OPERATORS

 $G \mid -- u1 < u2 ==> e1 < e2 : bool, q1 U q2 U {t1 = int, t2 = int}$

IF STATEMENTS

FUNCTION APPLICATION

FUNCTION DECLARATION

(a, b are fresh type variables; not in G)

SOLVING CONSTRAINTS

- A solution to a system of type constraints is a substitution S
 - a **function** from *type variables* to *type schemes*
 - substitutions are defined on all type variables (a total function), but only some of the variables are actually changed:
 - \circ S(a) = a (for almost all variables a)
 - \circ S(a) = s (for some a and some type scheme s)
 - $dom(S) = set of variables s.t. S(a) \neq a$

SUBSTITUTIONS

- Given a substitution S, we can define a function S* from type schemes (as opposed to type variables) to type schemes:
 - S*(int) = int
 - $S*(s1 \rightarrow s2) = S*(s1) \rightarrow S*(s2)$
 - S*(a) = S(a)
 - For simplicity, next I will write S(s) instead of S*(s)
 - s denotes type schemes, whereas a, b, c denote type variables
 - This function replaces all type variables in a type scheme.

Composition of Substitutions

- Composition (U o S) applies the substitution S and then applies the substitution U:
 - $(U \circ S)(a) = U(S(a))$
- We will need to compare substitutions
 - T <= S if T is "more specific" than S
 - T <= S if T is "less general" than S
 - Formally: $T \leq S$ if and only if T = U o S for some U

COMPOSITION OF SUBSTITUTIONS

• Examples:

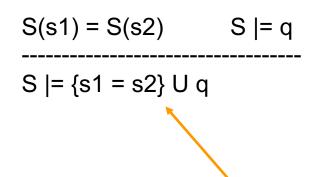

- example 1: any substitution is less general than the identity substitution I:
 - \circ S <= I because S = S \circ I
- example 2:
 - \circ S(a) = int, S(b) = c \rightarrow c
 - o T(a) = int, $T(b) = c \rightarrow c$, T(c) = int
 - \circ we conclude: T <= S
 - if T(a) = int, T(b) = int → bool then T is unrelated to S (neither more nor less general)

SOLVING A CONSTRAINT

Judgment format: S |= q(S is a solution to the constraints q)

any substitution is a solution for the empty set of constraints

a solution to an equation is a substitution that makes left and right sides equal

MOST GENERAL SOLUTIONS

- S is the principal (most general) solution of a set of constraints q if
 - $S \mid = q$ (S is a solution)
 - if T = q then $T \le S$ (S is the most general one)
- o Lemma: If q has a solution, then it has a most general one
- We care about principal solutions since they will give us the most general types for terms (polymorphism!)
- Exercise:

Prove: If q has a solution, then it has a most general one.

EXAMPLES

- Example 1
 - $q = \{a = int, b = a\}$
 - principal solution S:
 - \circ S(a) = S(b) = int
 - \circ S(c) = c (for all c other than a,b)

EXAMPLES

- Example 2
 - q = {a=int, b=a, b=bool}
 - principal solution S:
 - does not exist (there is no solution to q)
